INTRODUCTION

Solid-state peak power amplifier based on NLTL

Two operating regimes of a gyromagnetic NLTL:
(a) NLTL serves as HPM source (t_p >> T_osc)
(b) NLTL operates as a Magnetic Compression Line (MCL) with a peak power amplification (t_p ~ T_osc)

FWHM ~9 ns, T_osc ~0.9 ns (f = 1.1 GHz)
Input pulse amplitude ~300 kV
First peak amplitude ~450 kV

Romanchenko & Rostov calculations:

\[ V_{\text{max}} = \sqrt{2} V_{\text{in}} \]
Engineering evaluations

The power gain of the Magnetic Compression Line (MCL) is described by the expression:

\[ K_P = \frac{P_2^{\text{max}}}{P_1^{\text{max}}} = \frac{t_1(b)}{T_{\text{osc}}} \cdot \eta = K_c \cdot \eta \]  

where \( K_P \) is the power gain (the ratio of the peak powers of the output and input pulses), \( t_1(b) \) is the duration of the input pulse at the base level, \( T_{\text{osc}} \) is the period of oscillations generated in the line, \( \eta = \frac{W_2}{W_1} \) is the conversion efficiency of the pulse, which is equal to the ratio of the energies of the output and input pulses, and \( K_c = \frac{t_1(b)}{T_{\text{osc}}} \) is the pulse time compression coefficient.

For \( K_P = 2 \) and \( \eta \approx 0.5–0.7 \), the optimal compression coefficient \( K_c \) from (1) should be in the range of \( \approx 3–4 \). This requires a proportional increase in the oscillation frequency in the line by increasing the azimuthal magnetic field \( H_\theta \) in ferrite rings since \( T_{\text{osc}} \approx \frac{1}{H_\theta} \). Taking into account \( K_P = 2 \) (an increase in current pulse amplitude in the line by \( \approx 1.4 \) times), the necessary increase in the azimuthal field during the transition from the previous stage of pulse amplification to the next one is achieved by reducing the diameters of the line conductors and ferrite rings by \( \approx 2.0–2.8 \) times.
Input pulse: S–500 generator

Output parameters of the S-500 generator

- Loads: 40–125 Ω
- Peak voltage: 500–900 kV
- FWHM: ~7 ns
- Peak power: ~6 GW
- Burst PRF: up to 1 kHz

SOS parameters

- Cutoff current: ~14 kA
- Cutoff time: ~2 ns
- Breaking power: ~13 GW
- (dI/dt) max: ~7 kA/ns
- EEW: ~1 kA/ns
- POS: ~10 kA/ns

Electrical circuit of the S-500 generator: 1 – elements of the DFL charging unit, 2 – DFL–SOS unit, 3 – transmission line with ferrite sharpener FS and load R
SOS unit of S–500 generator

SOS unit (a), SOS diode (b), and elementary SOS diode (c). Total number of the diode structures – 3648 pieces.

Reverse current through each branch of the SOS
Two-stage compressor

MCL – Magnetic Compression Line \((t_p \sim T_{osc})\)

Parameters of the compression system. \(D\) and \(d\) – diameters of the outer \((D)\) and inner \((d)\) conductors of the line, \(\rho\) – wave impedance of the line calculated at \(\varepsilon_{oil} = 2.25\), \(D_f\) and \(d_f\) – outer \((D_f)\) and inner \((d_f)\) diameters of the ferrite rings, \(\Delta H_Z\) – range of variation of the bias magnetic field in the solenoid.

</table>
Limitations of the method

- Since one line increases the peak power ~2 times, the higher gain values are realized when connecting the lines in series.
- At the transition from the previous stage of amplification to the next one, the input pulse duration is reduced, which requires a proportional decrease in the period of oscillations in the line by reducing its transverse dimensions.
- The main limitation of the described method is an inevitable increase in electric and magnetic fields in the lines during the pulse energy compression in time.

- Increase in electric field to units of MV/cm leads to breakdown of the lines.
- Decrease in $H_z/H_\theta$ value reduces the power gain $K_p$. 

...
Four-stage MCL system
Conclusions

- The paper shows the possibility of creating **picosecond solid-state generators with a peak power of tens of GW**. In the proposed approach, an input pulse of nanosecond duration from a solid-state SOS generator is amplified in power and reduced in duration by a four-stage magnetic compressor on ferrite gyromagnetic lines.

- In the approach, the **line of each stage operates in the Magnetic Compression Line (MCL) mode**, which is realized at close values of the input pulse duration and the period of oscillations generated in the line.

- The most important feature of the approach is that **neither closing nor opening switching elements are required** in the pulse compression system. The pulse amplification in power and its compression in time occur automatically during the passage of the pulse along the line.

- The record high value of the voltage rise rate of **26 MV/ns** was achieved for electric pulse generators of any type.

- The record high values of the peak power (**77 GW**) and its rise rate (**1.6 TW/ns**) were achieved for solid-state pulsed power systems.
